

***Unit 7***  
***Logical Database Design***  
***With Normalization***

# Normalization in Context

# ***Introduction***

# ***Logical Database Design***

- We are given a set of tables specifying the database
  - The base tables, which probably are the community (conceptual) level
- They may have come from some ER diagram or from somewhere else
- We will need to examine whether the specific choice of tables is good for
  - **Storing the information needed**
  - **Enforcing constraints (business rules)**
  - **Avoiding anomalies, such as redundancies**
- If there are problems to address, we may want to **restructure the database, of course not losing any information**
- Let us quickly review an example from “long time ago”

# ***Lossless-Join Decomposition***

# ***A Fragment Of A Sample Relational Database***

R	Name	<u>SSN</u>	DOB	Grade	Salary
	A	121	2367	2	80
	A	132	3678	3	70
	B	101	3498	4	70
	C	106	2987	2	80

- Business rule, that is a semantic constraint, (one among several):
  - The value of Salary is determined only by the value of Grade
- Comment:
  - We may keep track of the various Grades for more than just computing salaries, though we do not show it
  - For instance, DOB and Grade together determine the number of vacation days, which may therefore be different for SSN 121 and 106

# Anomalies

Name	<u>SSN</u>	DOB	Grade	Salary
A	121	2367	2	80
A	132	3678	3	70
B	101	3498	4	70
C	106	2987	2	80

- “If Grade = 2 then Salary = 80” is written twice
- There are additional problems with this design.
  - We are unable to store the Salary for a Grade that does not currently exist for any employee.
  - For example, we cannot store that Grade = 1 implies Salary = 90
  - For example, if employee with SSN = 132 leaves, we forget which Salary should be paid to employee with Grade = 3
  - We could perhaps invent a fake employee with such a Grade and such a Salary, but this brings up additional problems, e.g.,  
What is the SSN of such a fake employee? **It cannot be NULL as SSN is the primary key**

# ***Better Representation Of Information***

- The problem can be solved by replacing one table

R	Name	<u>SSN</u>	DOB	Grade	Salary
	A	121	2367	2	80
	A	132	3678	3	70
	B	101	3498	4	70
	C	106	2987	2	80

by two tables

S	Name	<u>SSN</u>	DOB	Grade
	A	121	2367	2
	A	132	3678	3
	B	101	3498	4
	C	106	2987	2

T	<u>Grade</u>	Salary
	2	80
	3	70
	4	70

# ***Decomposition***

- `SELECT INTO S  
Name, SSN, DOB, Grade  
FROM R;`
- `SELECT INTO T  
Grade, Salary  
FROM R;`

# ***Better Representation Of Information***

- And now we can
  - Store “If Grade = 3 then Salary = 70”, even after the last employee with this Grade leaves
  - Store “If Grade = 2 then Salary = 90”, planning for hiring employees with Grade = 1, while we do not yet have any employees with this Grade

S	Name	<u>SSN</u>	DOB	Grade
	A	121	2367	2
	B	101	3498	4
	C	106	2987	2

T	<u>Grade</u>	Salary
	1	90
	2	80
	3	70
	4	70

# No Information Was Lost

- Given S and T, we can **reconstruct R** using **natural join**

S	Name	<u>SSN</u>	DOB	Grade
	A	121	2367	2
	A	132	3678	3
	B	101	3498	4
	C	106	2987	2

T	<u>Grade</u>	Salary
	2	80
	3	70
	4	70

```
SELECT INTO R
Name, SSN, DOB, S.Grade AS Grade, Salary
FROM T, S
WHERE T.Grade = S.Grade;
```

R	Name	<u>SSN</u>	DOB	Grade	Salary
	A	121	2367	2	80
	A	132	3678	3	70
	B	101	3498	4	70
	C	106	2987	2	80

# Natural Join

- Given several tables, say  $R_1, R_2, \dots, R_n$ , their **natural join** is computed using the following “template”:

**SELECT INTO R**

one copy of each column name

**FROM**  $R_1, R_2, \dots, R_n$

**WHERE** equal-named columns have to be equal

- The intuition is that  $R$  was “decomposed” into  $R_1, R_2, \dots, R_n$  by appropriate **SELECT** statements, and now we are putting them back together to reconstruct the original  $R$

# ***NATURAL JOIN in SQL***

- One can “naturally join” two tables in SQL using a new operation
- `SELECT *  
FROM R1  
NATURAL JOIN R2;`
- Of course, this can be done using standard SELECT statement appropriately constructed

```
SELECT ...  
FROM R1, R2  
WHERE ...
```

# Natural Join And Lossless Join Decomposition

- **Natural Join** is:
  - Cartesian join with condition of equality on corresponding columns
  - Only one copy of each column is kept
- **“Lossless join decomposition”** is another term for information not being lost, that is we can reconstruct the original table by “combining” information from the two new tables by means of natural join 
- This does not necessarily always hold
- We will have more material about this later
- Here we just observe that our decomposition satisfied this condition at least in our example

# ***Intuition On How To Decompose***

# Revisiting The Problem

- Let us look at

R	Name	<u>SSN</u>	DOB	Grade	Salary
	A	121	2367	2	80
	A	132	3678	3	70
	B	101	3498	4	70
	C	106	2987	2	80
	A	132	3678	3	70
	B	101	3498	4	70

- The problem is **not** that there are duplicate rows
- The problem is the same as before, business rule assigning Salary to Grade is written a number of times
- So how can we “generalize” the problem?

# Stating The Problem In General

R	Name	<u>SSN</u>	DOB	Grade	Salary
	A	121	2367	2	80
	A	132	3678	3	70
	B	101	3498	4	70
	C	106	2987	2	80
	A	132	3678	3	70
	B	101	3498	4	70

- We have a problem whenever we have two sets of columns X and Y (here X is just Grade and Y is just Salary), such that
  1. **X does not contain a key either primary or unique** (so possibly there could be several/many **non-identical** rows with the same value of X)
  2. **Whenever two rows are equal on X, they must be equal on Y**
- Why a problem: the business rule specifying how X “forces” Y is “embedded” in different rows and therefore
  - Inherently written redundantly
  - Cannot be stored by itself

# *What Did We Do?*

## *Think $X = \text{Grade}$ And $Y = \text{Salary}$*

- We had a table

- We replaced this one table by two tables

- ***This is only intuition and not a general procedure***

# ***Normalization***

# ***Logical Database Design***

- We will discuss techniques for dealing with the above issues
- Formally, we will study **normalization** (decompositions as in the above example) and **normal forms** (forms for relation specifying some “niceness” conditions)
- There will be three very important issues of interest:
  - Removal of redundancies
  - Lossless-join decompositions
  - Preservation of dependencies
- We will understand and learn the material mostly through comprehensive examples
- But everything will be precisely defined
- Algorithms for the general case will be fully and precisely given

# ***Several Passes On The Material***

- IT practitioners do it (mostly) differently than the way computer scientists like to do it
- **Pass 1:** Focus on how IT practitioners do it or at least like to talk about it

Ad-hoc treatment, but good for building intuition and having common language and concepts with IT people

- **Pass 2:** Focus on how computer scientists like to do or at least can do it this way if they want to

Good for actually using algorithms that guarantee correct results

# ***The Topic Is Normalization And Normal Forms***

- Normalization deals with “reorganizing” a relational database by, generally, breaking up tables (relations) to remove various anomalies
- We start with the way practitioners think about it
- We will proceed by means of a simple example, which is rich enough to understand what the problems are and how to think about fixing them

# Normal Forms

- **A normal form applies to a table/relation schema, not to the whole database schema**
- So the question is individually asked about a table: is it of some specific desirable normal form?
- The ones you need to know about in increasing order of “quality” and complexity:
  - First Normal Form (**1NF**); essentially states that we have a table/relation (useful violation: put an array in a field in a row)
  - Second Normal Form (**2NF**); intermediate form in some obsolete algorithms (we will ignore)
  - Third Normal Form (**3NF**); very important; a final form
  - Boyce-Codd Normal Form (**BCNF**); very important in theory (but less used in practice and we will understand why); a final form
  - Fourth Normal Form (**4NF**); a final form but generally what is good about it beyond previous normal forms is easily obtained without formal treatment
- There are additional ones, which are more esoteric, and which we will not cover

# ***Example***

## ***Our Example***

- We will deal with a very small fragment of a database dealing with a university
- We will make some assumptions in order to focus on the points that we need to learn
- We will identify people completely by their first names, which will be like Social Security Numbers
  - That is, whenever we see a particular first name more than once, such as Fang or Allan, this will always refer to the same person: there is only one Fang in the university, etc.

# ***Our New Example***

- We are looking at a single table in our database
- It has the following columns
  - S, which is a Student
  - B, which is the Birth Year of the Student
  - C, which is a Course that the student took
  - T, which is the Teacher who taught the Course the Student took
  - F, which is the Fee that the Student paid the Teacher for getting a good grade (just seeing whether you're awake😊)
- We will start with something that is not even a relation  
(Note this is similar to Employees having Children in Unit 2; a Student may have any number of (Course,Teacher,Fee) values

	S	B	C	T	F	C	T	F
	Fang	1990	DB	Zvi	1	OS	Allan	2
	John	1980	OS	Allan	2	PL	Marsha	4
	Mary	1990	PL	Vijay	1			

## ***Alternative Depiction***

- Instead of

	S	B	C	T	F	C	T	F
	Fang	1990	DB	Zvi	1	OS	Allan	2
	John	1980	OS	Allan	2	PL	Marsha	4
	Mary	1990	PL	Vijay	1			

you may see the above written as

	S	B	C	T	F
	Fang	1990	DB	Zvi	1
			OS	Allan	2
	John	1980	OS	Allan	2
			PL	Marsha	4
	Mary	1990	PL	Vijay	1

# ***First Normal Form (1NF)***

## **First Normal Form:**

### **A Table With A Fixed Number Of Column**

- Our “relation” **was not** a relation, because we are told that each Student may have taken any number of Courses
- Therefore, the number of columns is not fixed/bounded
- It is easy to make this a relation, getting

R	S	B	C	T	F
	Fang	1990	DB	Zvi	1
	John	1980	OS	Allan	2
	Mary	1990	PL	Vijay	1
	Fang	1990	OS	Allan	2
	John	1980	PL	Marsha	4

- Formally, we have a relation in **First Normal Form (1NF)**, this means that there are no structure within fields and the number of columns is fixed: in other words this is a relation, nothing new, defined for historical reasons
  - There are some variations to this definition, but we use this one

# ***Business Rules: Functional Dependencies***

# Our Business Rules (Constraints)

- Our enterprise has certain **business rules**
- We are told the following business rules
  1. A student can have only one birth year
  2. A teacher has to charge the same fee from every student he/she teaches.
  3. A teacher can teach only one course (perhaps at different times, different offerings, etc, but never another course)
  4. A student can take any specific course from one teacher only (or not at all)
- This means, that we are **guaranteed** that the information will always obey these business rules, as in the example

R	S	B	C	T	F
	Fang	1990	DB	Zvi	1
	John	1980	OS	Allan	2
	Mary	1990	PL	Vijay	1
	Fang	1990	OS	Allan	2
	John	1980	PL	Marsha	4

# ***Functional Dependencies*** ***(Abbreviation: FDs)***

- These rules can be formally described using ***functional dependencies***

- We assume for now that there are no NULLS
- Let P and Q be sets of columns, then:

P ***functionally determines*** Q, written  $P \rightarrow Q$

if and only if

any two rows that are equal on (all the attributes in) P  
must be equal on (all the attributes in) Q

- In simpler terms, informally, it means that:

***If a value of P is specified, it “forces” some (specific) value of Q; in other words: Q is a function of P***

- In our old example we looked at  $\text{Grade} \rightarrow \text{Salary}$

# Functional Dependencies (Abbreviation: FDs)

- It is possible to extend the definition to the case where NULLs exist

- Let P and Q be sets of columns, then:

P **functionally determines** Q, written  $P \rightarrow Q$

if and only if

1. There are no NULLs in the columns of P

2. Any two rows that are equal on (all the attributes in) P must be equal on all the attributes of Q, where here NULL is treated like any “real attribute”

- Example below, for simplicity, P and Q are single columns

	O	P	Q
A		10	x
B		20	y
C		20	y
D		30	NULL
E		30	NULL

## ***Our Given Functional Dependencies***

R	S	B	C	T	F
	Fang	1990	DB	Zvi	1
	John	1980	OS	Allan	2
	Mary	1990	PL	Vijay	1
	Fang	1990	OS	Allan	2
	John	1980	PL	Marsha	4

### ■ Our rules

1. A student can have only one birth year:  $S \rightarrow B$
2. A teacher has to charge the same fee from every student he teaches :  $T \rightarrow F$
3. A teacher can teach only one course (perhaps at different times, different offerings, etc., but never another course) :  $T \rightarrow C$
4. A student can take a course from one teacher only:  $SC \rightarrow T$

# ***Primary Keys***

## Possible Primary Key

- Our rules:  $S \rightarrow B$ ,  $T \rightarrow F$ ,  $T \rightarrow C$ ,  $SC \rightarrow T$
- ST is a possible primary key, because given ST
  1. S determines B
  2. T determines F
  3. T determines C
- A part of ST is not sufficient
  1. From S, we cannot get T, C, or F
  2. From T, we cannot get S or B

R	<u>S</u>	B	C	<u>I</u>	F
	Fang	1990	DB	Zvi	1
	John	1980	OS	Allan	2
	Mary	1990	PL	Vijay	1
	Fang	1990	OS	Allan	2
	John	1980	PL	Marsha	4

## Possible Primary Key

- Our rules:  $S \rightarrow B$ ,  $T \rightarrow F$ ,  $T \rightarrow C$ ,  $SC \rightarrow T$
- SC is a possible primary key, because given SC
  1. S determines B
  2. SC determines T
  3. T determines F (we can now use SC to determine F because of rule 2)
- A part of SC is not sufficient
  1. From S, we cannot get T, C, or F
  2. From C, we cannot get B, S, T, or F

R	<u>S</u>	B	<u>C</u>	T	F
	Fang	1990	DB	Zvi	1
	John	1980	OS	Allan	2
	Mary	1990	PL	Vijay	1
	Fang	1990	OS	Allan	2
	John	1980	PL	Marsha	4

# Possible Primary Keys

- Our rules:  $S \rightarrow B$ ,  $T \rightarrow F$ ,  $T \rightarrow C$ ,  $SC \rightarrow T$
- ST can serve as primary key, in effect:
  - $ST \rightarrow SBCTF$
  - This sometimes just written as  $ST \rightarrow BCF$ , since always  $ST \rightarrow ST$  (columns determine themselves)
- SC can serve as primary key, in effect:
  - $SC \rightarrow SBCTF$
  - This sometimes just written as  $SC \rightarrow BTF$ , since always  $SC \rightarrow SC$  (columns determine themselves)

# ***We Choose The Primary Key***

- We choose SC as ***the primary key***
- This choice is arbitrary, but perhaps it is more intuitively justifiable than ST
- For the time being, we ignore the other possible primary key (ST)

R	<u>S</u>	B	<u>C</u>	T	F
	Fang	1990	DB	Zvi	1
	John	1980	OS	Allan	2
	Mary	1990	PL	Vijay	1
	Fang	1990	OS	Allan	2
	John	1980	PL	Marsha	4

## ***Duplicate Rows Are Not A Problem***

R	<u>S</u>	B	<u>C</u>	T	F
	Fang	1990	DB	Zvi	1
	John	1980	OS	Allan	2
	Mary	1990	PL	Vijay	1
	Fang	1990	OS	Allan	2
	John	1980	PL	Marsha	4

R	<u>S</u>	B	<u>C</u>	T	F
	Fang	1990	DB	Zvi	1
	John	1980	OS	Allan	2
	Mary	1990	PL	Vijay	1
	Fang	1990	OS	Allan	2
	John	1980	PL	Marsha	4
	Mary	1990	PL	Vijay	1

- The two tables store the same information and both obey all the business rules, note that (Mary,PL) fixes all values

# Review

- To just review this
- Because  $S \rightarrow B$ , given a specific  $S$ , either it does not appear in the table, or wherever it appears it has the same value of  $B$ 
  - John has 1980, everywhere it appears
  - Lilian does not have  $B$  anywhere (in fact she does not appear in the relation)
- Because  $SC \rightarrow BTF$  (and therefore  $SC \rightarrow SCBTF$ , as of course  $SC \rightarrow SC$ ), given a specific  $SC$ , either it does not appear in the table, or wherever it appears it has the same value of  $BTF$ 
  - Mary,PL has 1990,Vijay,1, everywhere it appears
  - Mary,OS does not appear

# ***Classifying Functional Dependencies***

## ***Desirable: Dependencies From a Full Key***

- Consider a relation  $R$  with a functional dependency  $X \rightarrow Y$  where
  - $X$  and  $Y$  are sets of attributes
  - $X$  and  $Y$  are disjoint (to simplify the presentation for now)
- We will say that  $X \rightarrow Y$  is **from a full key** if  $X$  contains a key of  $R$
- To remind,  $X$  is a **key** of  $R$  if any two tuples that are equal on  $X$  are equal on all fields
  - In other words, the two tuples are identical

# Drawing Functional Dependencies

- Each column in a box.
- Our key (there could be more than one) is chosen to be the primary key and its boxes have thick borders and it is in the left part of the rectangle; another could be chosen
- Above the boxes, we have functional dependencies **“from the full key”**
- Below the boxes, we have functional dependencies **“not from the full key”**
- Colors of lines are not important, but good for explaining

# Classification Of Dependencies

- The three “not from the full key” dependencies are classified as:
- **Partial dependency:** From a part of the primary key to outside the key
- **Transitive dependency:** From outside the key to outside the key (this is our working definition, formally need to say something different which we will do for completeness next)
- Also, we will generalize this definition later
- **Into key dependency:** From outside the key into (all or part of) the key

# ***Formal Definition of “Transitive Dependency”***

- We have in our relation

$CS \rightarrow T$

$T \rightarrow F$

$CS \rightarrow F$

- Functional dependency  $CS \rightarrow F$  can be “decomposed” into

$CS \rightarrow T$

$T \rightarrow F$

- In fact and formally,  $CS \rightarrow F$  is a ***transitive closure*** of  $CS \rightarrow T$  and  $T \rightarrow F$ , so  $CS \rightarrow F$  and not  $T \rightarrow F$  is called ***transitive dependency***

But we focus on  $T \rightarrow F$  as it is the one causing problems

# ***Anomalies***

# Anomalies

- ***These “not from the full key” dependencies cause the design to be bad***
  - ***Inability to store important information***
  - ***Redundancies***
- Imagine a new Student appears who has not yet registered for a course
  - This S has a specific B (birth year), but this cannot be stored in the table as we do not have a value of C ( Course) yet, and the attributes of the primary key cannot be NULL
- Imagine that Mary withdrew from the only Course she has
  - We have no way of storing her B
- Imagine that we “erase” the value of C in the row stating that Fang was taught by Allan
  - We will know that this was OS, as John was taught OS by Allan, and every teacher teaches only one subject, so we had a redundancy; and whenever there is a redundancy, there is potential for inconsistency

## Review Of Our Example

R	<u>S</u>	B	<u>C</u>	T	F
	Fang	1990	DB	Zvi	1
	John	1980	OS	Allan	2
	Mary	1990	PL	Vijay	1
	Fang	1990	OS	Allan	2
	John	1980	PL	Marsha	4

### ■ Our rules

- A student can have only one birth year:  $S \rightarrow B$
- A teacher has to charge the same fee from every student he/she teaches :  $T \rightarrow F$
- A teacher can teach only one course (perhaps at different times, different offerings, etc., but never another course) :  $T \rightarrow C$
- A student can take a course from one teacher only :  $SC \rightarrow T$

# ***Incorrect Decomposition (Not A Lossless Join Decomposition)***

- Assume we replaced

R	Name	<u>SSN</u>	DOB	Grade	Salary
	A	121	2367	2	80
	A	132	3678	3	70
	B	101	3498	4	70
	C	106	2987	2	80

with two tables.

S	Name	DOB	Grade	Salary
	A	2367	2	80
	A	3678	3	70
	B	3498	4	70
	C	2987	2	80

T	<u>SSN</u>	Salary
	121	80
	132	70
	101	70
	106	80

- We cannot answer the question what is the Name for SSN = 121 (we lost information), so cannot decompose like this

## ***Second Normal Form (2NF)***

Dennis will jump to page 87. Students may read the intervening pages as an option.

## ***Our Example Again***

	<u>S</u>	B	<u>C</u>	T	F
	Fang	1990	DB	Zvi	1
	John	1980	OS	Allan	2
	Mary	1990	PL	Vijay	1

	Fang	1990
	John	1980
	Mary	1990

## **Second Normal Form:** **1NF And No Partial Dependencies**

- Each of the tables in our database is in Second Normal Form
- Second Normal Form means:
  - First Normal Form
  - No Partial dependencies
- The above is checked individually for each table
- Furthermore, our decomposition was a lossless join decomposition
- This means that by “combining” all the tables using the natural join, we get exactly the original table back
- This is checked “globally”; we do not discuss how this is done generally, but intuitively clearly true in our simple example

# *Transitive Dependency: $T \rightarrow F$*

## ***Third Normal Form:*** ***2NF And No Transitive Dependencies***

- Each of the tables in our database is in Third Normal Form
- Third Normal Form means:
  - Second Normal Form (therefore in 1NF and no partial dependencies)
  - No transitive dependencies
- The above is checked individually for each table
- Furthermore, our decomposition was a lossless join decomposition
- This means that by “combining” all the tables we get exactly the original table back
- This is checked “globally”; we do not discuss how this is done generally, but intuitively clearly true in our simple example

# Anomaly

	<u>S</u>	<u>C</u>	T
	Fang	DB	Zvi
	John	OS	Allan
	Mary	PL	Vijay
	Fang	OS	Allan
	John	PL	Marsha

- We are worried about decomposing by “pulling out” C and getting CS and TC, as we are pulling out a part of the key
- But we can actually do it
- We see next how

## *An Alternative Primary Key: TS*

	<u>S</u>	C	<u>I</u>
	Fang	DB	Zvi
	John	OS	Allan
	Mary	PL	Vijay
	Fang	OS	Allan
	John	PL	Marsha

- Note that TS could also serve as primary key for this table SCT since by looking at the FD we have:  $T \rightarrow C$ , we see that TS functionally determines everything, that is it determines all the attributes TSC
- Recall, that TS could have been chosen as the primary key of the original table

# Anomaly

	<u>S</u>	C	<u>I</u>
	Fang	DB	Zvi
	John	OS	Allan
	Mary	PL	Vijay
	Fang	OS	Allan
	John	PL	Marsha

- Now our anomaly is a partial dependency, which we know how to handle

## **Boyce-Codd Normal Form:**

### **1NF And All Dependencies From Full Key**

- Each of the tables in our database is in Boyce-Codd Normal Form
- Boyce-Codd Normal Form (BCNF) means:
  - First Normal Form
  - Every non-trivial functional dependency is from a full key (that is, if  $X \rightarrow Y$  holds then  $X$  contains a key of the relation)
- A table is BCNF is automatically in 3NF (p. 77 ,skipped) as no bad dependencies are possible
- Usually, the procedure for third normal form will go to Boyce-Codd Normal Form.
- Furthermore, our decomposition was a lossless join decomposition
- This means that by “combining” all the tables we get exactly the original table back.
- Jump to page 103.

# ***A New Issue: Maintaining Database Correctness And Preservation Of Dependencies***

- We can understand this issue just by looking at the table which we decomposed last
- We will not use drawings but write the constraints that needed to be satisfied in narrative
- We will examine an update to the database and look at two scenarios
- When we have one “imperfect” 3NF table SCT
- When we have two “perfect” BCNF tables ST and CT
- We will attempt an incorrect update and see how to detect it under both scenarios

## ***Our Tables (For The Two Cases)***

- SCT satisfies:  $SC \rightarrow T$  and  $ST \rightarrow C$ : keys SC and ST

	<u>S</u>	<u>C</u>	T
	Fang	DB	Zvi
	John	OS	Allan
	Mary	PL	Vijay
	Fang	OS	Allan
	John	PL	Marsha

- ST does not satisfy anything: key ST
- CT satisfies  $T \rightarrow C$ : key T

	<u>S</u>	<u>T</u>
	Fang	Zvi
	John	Allan
	Mary	Vijay
	Fang	Allan
	John	Marsha

	<u>C</u>	<u>T</u>
	DB	Zvi
	OS	Allan
	PL	Vijay
	OS	Allan
	PL	Marsha

## ***An Insert Attempt***

- A user wants to specify that now John is going to take PL from Vijay
- If we look at the database, we realize this update should not be permitted because
  - John can take PL from at most one teacher
  - John already took PL (from Marsha)
- But can the system figure this out just by checking whether FDs continue being satisfied?
- Let us find out what will happen in each of the two scenarios
- But we now pay attention to all the keys and not just the chosen primary key

## Scenario 1: SCT

- We maintain SCT, knowing that its keys are SC and ST

- Before the INSERT, constraints are satisfied; required keys are indeed keys

	<u>S</u>	<u>C</u>	T
	Fang	DB	Zvi
	John	OS	Allan
	Mary	PL	Vijay
	Fang	OS	Allan
	John	PL	Marsha

- **After the INSERT, constraints are not satisfied; SC is no longer a key**
- INSERT rejected after the constraint is checked

	<u>S</u>	<u>C</u>	T
	Fang	DB	Zvi
	John	OS	Allan
	Mary	PL	Vijay
	Fang	OS	Allan
	John	PL	Marsha
	John	PL	Vijay

## Scenario 2: ST And CT

- We maintain ST, knowing that its key is S
- We maintain CT, knowing that its key is T

- Before the INSERT, constraints are satisfied; required keys are indeed keys

	<u>S</u>	<u>I</u>		C	<u>I</u>
	Fang	Zvi		DB	Zvi
	John	Allan		OS	Allan
	Mary	Vijay		PL	Vijay
	Fang	Allan		OS	Allan
	John	Marsha		PL	Marsha

- After the INSERT, constraints are still satisfied; keys remain keys

	<u>S</u>	<u>I</u>		C	<u>I</u>
	Fang	Zvi		DB	Zvi
	John	Allan		OS	Allan
	Mary	Vijay		PL	Vijay
	Fang	Allan		OS	Allan
	John	Marsha		PL	Marsha
	John	Vijay		PL	Vijay

- But the INSERT **must** still be rejected

## Scenario 2: What To Do?

- The INSERT must be rejected
- This bad insert cannot be discovered as bad by examining only what happens in each individual table
- The formal term for this is: **dependencies are not preserved**
- When dependencies are not preserved that does not mean that they are “lost” in any sense
- This means that they still need to be satisfied by the database, but checking what happens in each relation individually is not sufficient
- **So we need to perform non-local tests to check updates for validity**
- For example in our case, combine ST and CT and reconstruct SCT

# ***A Very Important Design Principle***

- Generally, normalize up to 3NF and not up to BCNF
  - So the database is not fully normalized
- Luckily, when you do this, frequently you “automatically” get BCNF
  - But not in our example, which I set up on purpose so this does not happen

# ***Multivalued Dependencies***

- To have a smaller example, we will look at this separately, not by extending our previous example
  - Otherwise, it would become too big
- In the application, we store information about Courses (C), Teachers (T), and Books (B)
- Each course has a set of books that have to be assigned during the course
- Each course has a set of teachers that are qualified to teach the course
- Each teacher, when teaching a course, has to use the set of the books that has to be assigned in the course

## ***An Example table***

	C	T	B
	DB	Zvi	Oracle
	DB	Zvi	Linux
	DB	Dennis	Oracle
	DB	Dennis	Linux
	OS	Dennis	Windows
	OS	Dennis	Linux
	OS	Jinyang	Windows
	OS	Jinyang	Linux

- This instance (and therefore the table in general) does not satisfy any functional dependencies
  - CT does not functionally determine B
  - CB does not functionally determine T
  - TB does not functionally determine C

# Redundancies

	C	T	B
	DB	Zvi	Oracle
	DB	Zvi	Linux
	DB	Dennis	?
	DB	Dennis	?
	OS	Dennis	Windows
	OS	Dennis	Linux
	OS	Jinyang	?
	OS	Jinyang	?

	C	T	B
	DB	Zvi	Oracle
	DB	?	Linux
	DB	Dennis	Oracle
	DB	?	Linux
	OS	Dennis	Windows
	OS	?	Linux
	OS	Jinyang	Windows
	OS	?	Linux

- There are obvious redundancies
- In both cases, we know exactly how to fill the missing data if it was erased
- We decompose to get rid of anomalies

	OS	Linux

# ***Multivalued Dependencies And 4NF***

- We had the following situation
- For each value of C there was
  - A set of values of T
  - A set of values of B
- Such that, every T of C had to appear with every B of C  
This is stated here rather loosely, but it is clear what it means
- The notation for this is:  $C \twoheadrightarrow T \mid B$
- The tables CT and CB are in ***Fourth Normal Form (4NF)***
- We do not define formally here

# ***Algorithmic Techniques***

## ***Introduction***

## ***Now: To Algorithmic Techniques***

- ***We proceeded by doing plausible actions but we cannot do that in general***
- ***So what we did was not the procedure to follow in general***
- So far, our treatment was not algorithmic and we just looked at an interesting case exploring within the context of that case 3 issues
  1. Avoiding (some) redundancies by converting tables to 3NF (and sometimes getting BCNF)
  2. Preserving dependencies/constraints by making sure that dependencies (business rules) can be easily checked and enforced
  3. Making sure that the decomposition of tables to obtain tables in better form does not cause us to lose information (lossless join) decomposition

## ***Now: To Algorithmic Techniques***

- While we looked at examples to build up an intuition, we did not have an algorithmic procedure to deal with the design issues
- We now continue with building up intuition and actually learning an algorithmic procedure
- This is the procedure you will use in the course on all the questions you will be asked to answer
- So the drawings we had are good to know, but we will not use them for normalization

# ***Closures Of Sets Of Attributes***

# ***Closures Of Sets Of Attributes (Column Names)***

- Closure of a set of attributes is an easy to use and extremely powerful tool for everything that follows
- “On the way” we may review some concepts
- We return to our old example, in which we are given a table with three columns (attributes)
  - Employee (E, for short, meaning really the SSN of the employee)
  - Grade (G, for short)
  - Salary (S, for short)
- Satisfies:
  1.  $E \rightarrow G$
  2.  $G \rightarrow S$
- We would like to find all the keys of this table
- A key is a minimal set of attributes, such that the values of these attributes, “force” some values for all the other attributes

# Closures Of Sets Of Attributes

- In general, we have a concept of a **the closure of a set of attributes**
- Let  $X$  be a set of attributes, **then  $X^+$  is the set of all the attributes, whose values are forced by the values of  $X$**
- In our example
  - $E^+ = EGS$  (because given  $E$  we have the value of  $G$  and then because we have the value for  $G$  we have the value for  $S$ )
  - $G^+ = GS$
  - $S^+ = S$
- This is interesting because we have just showed that  $E$  is a key
- And here we could also figure out that this is the only key, as  $GS^+ = GS$ , so we will never get  $E$  unless we already have it
- Note that  $GS^+$  really means  $(GS)^+$  **and not  $G(S)^+$**

# Computing Closures Of Sets Of Attributes

- There is a very simple algorithm to compute  $X^+$

1. Let  $Y = X$

2. Whenever there is an FD, say  $V \rightarrow W$ , such that

1.  $V \subseteq Y$ , and

2.  $W - Y$  is not empty

- add  $W - Y$  to  $Y$

3. At termination  $Y = X^+$

- The algorithm is very efficient
- Each time we look at all the functional dependencies
  - Either we can apply at least one functional dependency and make  $Y$  bigger (the biggest it can be are all attributes), or
  - We are finished

## *Example*

- Let  $R = ABCDEGHIJK$
- Given FDs:
  1.  $K \rightarrow BG$
  2.  $A \rightarrow DE$
  3.  $H \rightarrow AI$
  4.  $B \rightarrow D$
  5.  $J \rightarrow IH$
  6.  $C \rightarrow K$
  7.  $I \rightarrow J$
- We will compute:  $ABC^+$ 
  1. We start with  $ABC^+ = ABC$
  2. Using FD number 2, we now have:  $ABC^+ = ABCDE$
  3. Using FD number 6, we now have  $ABC^+ = ABCDEK$
  4. Using FD number 1, we now have  $ABC^+ = ABCDEKG$

No FD can be applied productively anymore and we are done

# ***Keys***

# Keys Of Tables

- **The notion of an FD allows us to formally define keys**
- Given R (relation schema which is always denoted by its set of attributes), satisfying a set of FDs, **a set of attributes X of R is a key, if and only if:**
  - $X^+ = R$ .
  - For any  $Y \subseteq X$  such that  $Y \neq X$ , we have  $Y^+ \neq R$ .
- Note that if R does not satisfy any (nontrivial) FDs, then R is the only key of R
- A functional dependency  $P \rightarrow Q$  is “trivial” if  $Q \subseteq P$ : we saying something that is always true and not interesting
- Example,  $AB \rightarrow A$  is always true and does not say anything interesting
- Example, if a table is R(FirstName,LastName) without any functional dependencies, then its key is just the pair (FirstName,LastName)

# ***Keys of Tables***

- If we apply our algorithm to the EGS example given earlier, we can now just compute that E was (the only) key by checking all the subsets of {E,G,S}
- Of course, in general, our algorithm is not efficient, but in practice what we do will be very efficient (most of the time)

## *Example*

- Let  $R = ABCDEKGH IJ$
- Given FDs:
  1.  $K \rightarrow BG$
  2.  $A \rightarrow DE$
  3.  $H \rightarrow AI$
  4.  $B \rightarrow D$
  5.  $J \rightarrow IH$
  6.  $C \rightarrow K$
  7.  $I \rightarrow J$
- Then
  - $ABCH^+ = ABCDEGHIJK$
  - And  $ABCH$  is a key or maybe contains a key as a proper subset
  - We could check whether  $ABCH$  is a key by computing  $ABC^+$ ,  $ABH^+$ ,  $ACH^+$ ,  $BCH^+$  and showing that none of them is  $ABCDEGHIJK$

## ***Another Example: Airline Scheduling***

- We have a table PFDT, where
  - PILOT
  - FLIGHT NUMBER
  - DATE
  - SCHEDULED\_TIME\_of\_DEPARTURE
  
- The table satisfies the FDs. What is the key?
  - $F \rightarrow T$
  - $PDT \rightarrow F$
  - $FD \rightarrow P$

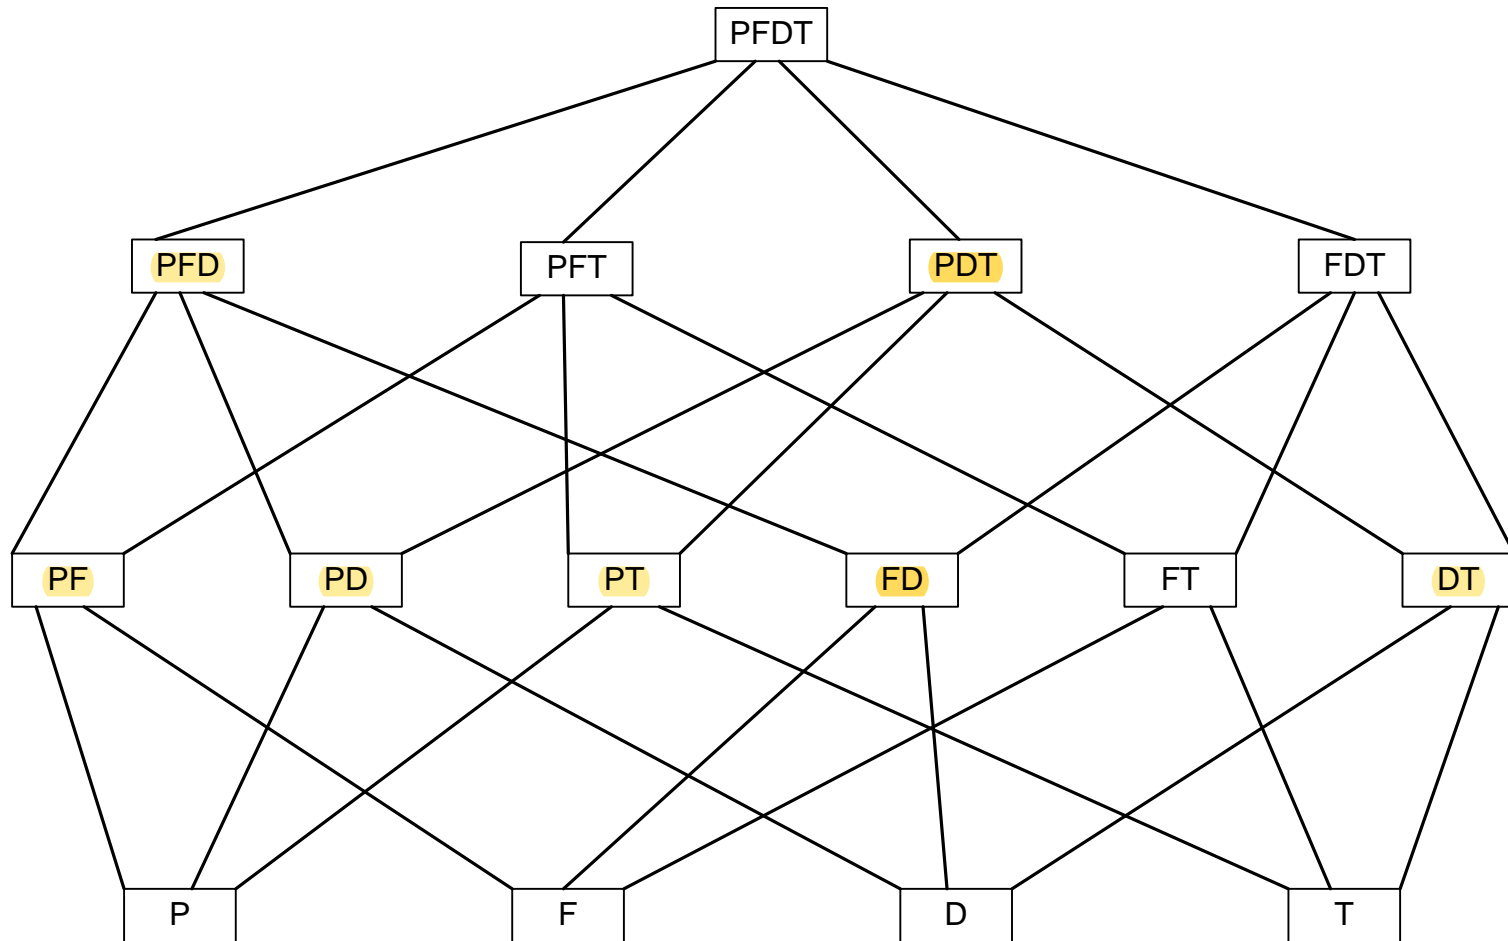

# ***Computing Keys***

- We will compute all the keys of the table
  - In general, this will be an exponential-time algorithm in the size of the problem
  - But there will be useful heuristic making this problem tractable in practice
  - We will introduce some heuristics here and additional ones later
- 
- We note that if some subset of attributes is a key, then no proper superset of it can be a key as it would not be minimal and would have superfluous attributes

# ***Lattice Of Sets Of Attributes***

- There is a natural structure (technically a lattice) to all the nonempty subsets of attributes
- I will draw the lattice here, in practice this is not done
  - Not necessary and too big
- We will look at all the non-empty subsets of attributes
- There are 15 of them:  $2^4 - 1$
- The structure is clear from the drawing

# ***Lattice Of Nonempty Subsets***

# Keys Of PFDT

- The algorithm proceeds from bottom up
- We first try all potential 1-attribute keys, by examining all 1-attribute sets of attributes
  - $P^+ = P$
  - $F^+ = FT$
  - $D^+ = D$
  - $T^+ = T$

There are no 1-attribute keys, so we prune the lattice by removing sets of 1 attribute

- Note, that the it is impossible for a key to have **both** F and T
  - Because if F is in a key, T will be automatically determined as it is included in the closure of F
- Therefore, we can eliminate as candidates all sets containing FT, including FT itself

# ***Keys Of PFDT***

- We try all potential 2-attribute keys
  - $PF^+ = PFT$
  - $PD^+ = PD$
  - $PT^+ = PT$
  - $FD^+ = FDPT$
  - $DT^+ = DT$

There is one 2-attribute key: DF

- We remove all other sets of 2 attributes
- We can assert DF is a key
- Note that as DF is a key no proper superset of it can be a key (because no single attribute is a key).

# ***Normalization By Decompositions Of Tables***

# ***Finding A Decomposition***

- Next, we will discuss by means of an example how to decompose a table into tables, such that
  1. The decomposition is lossless join
  2. Dependencies are preserved
  3. Each resulting table is in 3NF
- Although this will be described using an example, the example will be sufficiently general so that the general procedure will be covered
- There are similar procedures for finding such a decomposition, but this is the one that needs to be followed in the homework

# ***The EmToPrHoSkLoRo Table***

- The table deals with employees who use tools on projects and work a certain number of hours per week
- An employee may work in various locations and has a variety of skills
- All employees having a certain skill and working in a certain location meet in a specified room once a week
  
- The attributes of the table are:
  - Em: Employee
  - To: Tool
  - Pr: Project
  - Ho: Hours per week
  - Sk: Skill
  - Lo: Location
  - Ro: Room for meeting

## ***The FDs Of The Table***

- The table deals with employees who use tools on projects and work a certain number of hours per week
- An employee may work in various locations and has a variety of skills
- All employees having a certain skill and working in a certain location meet in a specified room once a week
- The table satisfies the following FDs (write on board):
  - Each employee uses a single tool:  $Em \rightarrow To$
  - Each employee works on a single project:  $Em \rightarrow Pr$
  - Each tool can be used on a single project only:  $To \rightarrow Pr$
  - An employee uses each tool for the same number of hours each week:  $EmTo \rightarrow Ho$
  - All the employees working in a location having a certain skill always work in the same room (in that location):  $SkLo \rightarrow Ro$
  - Each room is in one location only:  $Ro \rightarrow Lo$

## ***Sample Instance: Many Redundancies***

	Em	To	Pr	Ho	Sk	Lo	Ro

	Lakshmi	Oracle	Database	40	Economist	Buffalo	107

# 1: Getting A Minimal Cover

- We need to “simplify” our set of FDs to bring it into a “nicer” form, so called **minimal cover** or (sometimes called also **canonical cover**)
- But, of course, the “business rule” power has to be the same as we need to enforce the same business rules
- The algorithm for this will be covered later and it is very important
- The end result will be, which we will derive later is
  1.  $Em \rightarrow ToHo$
  2.  $To \rightarrow Pr$
  3.  $SkLo \rightarrow Ro$
  4.  $Ro \rightarrow Lo$
- From these we will build our tables directly.

## ***2: Creating Tables From a Minimal Cover***

- Create a table for each functional dependency
- We obtain the tables:
  1. EmToHo
  2. ToPr
  3. SkLoRo
  4. LoRo

### ***3: Removing Redundant Tables***

- LoRo is a subset of SkLoRo, so we remove it
- We obtain the tables:
  1. EmToHo
  2. ToPr
  3. SkLoRo

## ***4: Ensuring The Storage Of The Global Key (Of The Original Table)***

- To avoid loss of information , we need a table containing the global key
- Perhaps one of our tables contains such a key
- So we check if any of them already contains a key of EmToPrHoSkLoRo:

- |           |  |
|-----------|--|
| 1. EmToHo | $\text{EmToHo}^+ = \text{EmToHoPr}$ , does not contain a key |
| 2. ToPr   | $\text{ToPr}^+ = \text{ToPr}$ , does not contain a key       |
| 3. SkLoRo | $\text{SkLoRo}^+ = \text{SkLoRo}$ , does not contain a key   |

- We need to add a table whose attributes form a global key

## ***Finding Keys Using a Good Heuristic***

- Let us list the FDs again (or could have worked with the minimal cover, does not matter):
  - $Em \rightarrow To$
  - $Em \rightarrow Pr$
  - $To \rightarrow Pr$
  - $EmTo \rightarrow Ho$
  - $SkLo \rightarrow Ro$
  - $Ro \rightarrow Lo$
- We can classify the attributes into 4 classes:
  1. Appearing on both sides of FDs; here To, Lo, Ro.
  2. Appearing on left sides only; here Em, Sk.
  3. Appearing on right sides only; here Pr, Ho.
  4. Not appearing in FDs; here none.

# ***Finding Keys***

- Facts:
  - Attributes of class 2 and 4 must appear in every key
  - Attributes of class 3 do not appear in any key
  - Attributes of class 1 may or may not appear in keys
- An algorithm for finding keys relies on these facts
  - Unfortunately, in the worst case, exponential in the number of attributes
- Start with the attributes in classes 2 and 4, add as needed (going bottom up) attributes in class 1, and ignore attributes in class 3

## ***Finding Keys***

- In our example, therefore, every key must contain EmSk
- To see which attributes, if any, have to be added, we compute which attributes are determined by EmSk
- We obtain
  - $\text{EmSk}^+ = \text{EmToPrHoSk}$
- Therefore Lo and Ro are missing
- It is easy to see that the table has two keys
  - EmSkLo
  - EmSkRo

## ***4: Ensuring The Storage Of A Global Key***

- None of the tables contains either EmSkLo or EmSkRo.
- Therefore, one more table needs to be added. We have 2 choices for the final decomposition
  1. EmToHo; satisfying  $Em \rightarrow ToHo$ ; primary key: Em
  2. ToPr; satisfying  $To \rightarrow Pr$ ; primary key To
  3. SkLoRo; satisfying  $SkLo \rightarrow Ro$  and  $Ro \rightarrow Lo$ ; primary key SkLo or SkRo
  4. EmSkLo; not satisfying anything; primary key EmSkLoor
  1. EmToHo; satisfying  $Em \rightarrow ToHo$ ; primary key: Em
  2. ToPr; satisfying  $To \rightarrow Pr$ ; primary key To
  3. SkLoRo; satisfying  $SkLo \rightarrow Ro$  and  $Ro \rightarrow Lo$ ; primary key SkLo or SkRo
  4. EmSkRo ; not satisfying anything; primary key EmSkRO
- We have completed our process and got a decomposition with the properties we needed; actually more than one

## ***Properties Of The Decomposition***

- The table on the left lists the values of a key of the original table
- Each row corresponds to a row of the original table
- The other tables have rows that could be “glued” to the “key” table based on the given business rules and thus reconstruct the original table
- All the tables are in 3NF (and usually Boyce Codd normal form though this is not in general guaranteed)

## ***Computing A Minimal (Canonical) Cover***

Remember: this was a step we had just assumed  
had been done.

# Computing Minimal Cover

- What remains to be done is to learn how to start with a set of FDs and to “reduce” them to a “clean” set **with equivalent constraints power**
- This “clean” set is a minimal cover
- So we need to learn how to do that next
- We need first to understand better some properties of FDs

## ***Reminder: Functional Dependencies***

- Generally, if  $X$  and  $Y$  are sets of attributes, then  $X \rightarrow Y$  means:

Any two tuples (rows) that are equal on (the vector of attributes)  $X$

are also

equal on (the vector of attributes)  $Y$

- Note that this is not the same as the concept of a key (UNIQUE, PRIMARY KEY)
  - We do not insist that  $X$  determines everything
  - For instance we say that any two tuples that are equal on  $G$  are equal on  $S$ , but we **do not** say that any two tuples that are equal on  $G$  are “completely” equal (equal on all fields)

# An Example

- Functional dependencies are properties of a schema, that is, **all permitted** instances
- For practice, we will examine an instance

	A	B	C	D	E	F	G	H
	a1	b1	c1	d1	e1	f1	g1	h1
	a2	b1	c1	d2	e2	f2	g1	h1
	a2	b2	c3	d3	e3	f3	g1	h2
	a1	b1	c1	d1	e1	f4	g2	h3
	a1	b2	c2	d2	e4	f5	g2	h4
	a2	b3	c3	d2	e5	f6	g2	h3

1.  $A \rightarrow C$  No
2.  $AB \rightarrow C$  Yes
3.  $E \rightarrow CD$  Yes
4.  $D \rightarrow B$  No
5.  $F \rightarrow ABC$  Yes
6.  $H \rightarrow G$  Yes
7.  $H \rightarrow GE$  No
8.  $HGE \rightarrow GE$  Yes

# ***Relative Power Of Some FDs***

## ***$H \rightarrow G$ vs. $H \rightarrow GE$***

- Let us look at another example first
- Consider some table talking about employees in which there are three columns:
  1. Grade
  2. Bonus
  3. Salary
- Consider now two possible FDs (functional dependencies)
  1.  $\text{Grade} \rightarrow \text{Bonus}$
  2.  $\text{Grade} \rightarrow \text{Bonus Salary}$
- FD (2) is more restrictive, fewer relations will satisfy FD (2) than satisfy FD (1)
  - So FD (2) is stronger
  - Every relation that satisfies FD (2), must satisfy FD (1)
  - And we know this just because  $\{\text{Bonus}\}$  is a proper subset of  $\{\text{Bonus, Salary}\}$

## ***Relative Power Of Some FDs***

### ***$H \rightarrow G$ vs. $H \rightarrow GE$***

- An important note:  $H \rightarrow GE$  is always at least as powerful as  $H \rightarrow G$   
that is
- If a relation satisfies  $H \rightarrow GE$  it must satisfy  $H \rightarrow G$
- What we are really saying is that if  $GE = f(H)$ , then of course  $G = f(H)$
- An informal way of saying this: if being equal on  $H$  forces to be equal on  $GE$ , then of course there is equality just on  $G$
- More generally, if  $X, Y, Z$ , are sets of attributes and  $Z \subseteq Y$ ; then if  $X \rightarrow Y$  is true then  $X \rightarrow Z$  is true

# ***Relative Power Of Some FDs***

## ***$A \rightarrow C$ vs. $AB \rightarrow C$***

- Let us look at another example first
- Consider some table talking about employees in which there are three columns:
  1. Grade
  2. Location
  3. Salary
- Consider now two possible FDs
  1.  $\text{Grade} \rightarrow \text{Salary}$
  2.  $\text{Grade Location} \rightarrow \text{Salary}$
- FD (2) is less restrictive, more relations will satisfy FD (2) than satisfy FD (1)
  - So FD (1) is stronger
  - Every relation that satisfies FD (1), must satisfy FD (2)
  - And we know this just because  $\{\text{Grade}\}$  is a proper subset of  $\{\text{Grade}, \text{Salary}\}$

## ***Relative Power Of Some FDs***

### ***$A \rightarrow C$ vs. $AB \rightarrow C$***

- An important note:  $A \rightarrow C$  is always at least as powerful as  $AB \rightarrow C$

that is

- If a relation satisfies  $A \rightarrow C$  it must satisfy  $AB \rightarrow C$
- An informal way of saying this: if just being equal on A forces to be equal on C, then if we **in addition** know that there is equality on B also, of course it is still true that there is equality on C
- More generally, if X, Y, Z, are sets of attributes and  $X \subseteq Y$ ; then if  $X \rightarrow Z$  is true then  $Y \rightarrow Z$  is true

## *Trivial FDs*

- An FD  $X \rightarrow Y$ , where  $X$  and  $Y$  are sets of attributes is trivial

if and only if

$$Y \subseteq X$$

(Such an FD gives no constraints, as it is always satisfied, which is easy to prove)

- Example
  - Grade, Salary  $\rightarrow$  Grade is trivial
- A trivial FD does not provide any constraints
- Every relations that contains columns Grade and Salary will satisfy this FD: Grade, Salary  $\rightarrow$  Grade

# ***Decomposition And Union Of Some FDs***

- An FD  $X \rightarrow A_1 A_2 \dots A_m$ , where  $A_i$ 's are individual attributes

is equivalent to

the set of FDs:

$$X \rightarrow A_1$$

$$X \rightarrow A_2$$

...,

$$X \rightarrow A_m$$

- Example

FirstName LastName  $\rightarrow$  Address Salary

is equivalent to the set of the two FDs:

Firstname LastName  $\rightarrow$  Address

Firstname LastName  $\rightarrow$  Salary

# Logical Implications Of FDs

- It will be important to us to determine if a given set of FDs **forces** some other FDs to be true
- Consider again the EGS relation
- Which FDs are satisfied?
  - $E \rightarrow G$ ,  $G \rightarrow S$ ,  $E \rightarrow S$  are all true in the real world
- If the real world tells you only:
  - $E \rightarrow G$  and  $G \rightarrow S$
- Can you deduce on your own (and is it even always true?), **without understanding the semantics of the application**, that
  - $E \rightarrow S$ ?

# ***Logical implications Of FDs***

- Yes, by simple logical argument: transitivity
  1. Take any (set of) tuples that are equal on E
  2. Then given  $E \rightarrow G$  we know that they are equal on G
  3. Then given  $G \rightarrow S$  we know that they are equal on S
  4. So we have shown that  $E \rightarrow S$  must hold
- We say that  $E \rightarrow G$ ,  $G \rightarrow S$  ***logically imply***  $E \rightarrow S$  and we write
- $E \rightarrow G, G \rightarrow S \models E \rightarrow S$
- This means:
  - If a relation satisfies  $E \rightarrow G$  and  $G \rightarrow S$ ,
  - then
  - It must satisfy  $E \rightarrow S$

# Logical Implications Of FDs

- If the real world tells you only:
  - $E \rightarrow G$  and  $E \rightarrow S$ ,
- Can you deduce on your own, without understanding the application that
  - $G \rightarrow S$
- No, in fact, here is a counterexample:

EGS	<u>E</u>	G	S
	Alpha	A	1
	Beta	A	2

- This relation satisfies  $E \rightarrow G$  and  $E \rightarrow S$ , but violates  $G \rightarrow S$
- For intuitive explanation, think: G means Height and S means Weight

## Conclusion/Question

- Consider a relation EGS for which the three constraints  $E \rightarrow G$ ,  $G \rightarrow S$ , and  $E \rightarrow S$  **must all be obeyed**
- **It is enough** to make sure that the two constraints  $E \rightarrow G$  and  $G \rightarrow S$  are not violated
- **It is not enough** to make sure that the two constraints  $E \rightarrow G$  and  $E \rightarrow S$  are not violated
- But what to do in general, large, complex cases?

## ***Reminder: Closures Of Sets Of Attributes***

- We consider some relation schema, which is a set of attributes,  $R$  (say EGS, which could also write as  $R(EGS)$ )
- A set  $F$  of FDS for this schema (say  $E \rightarrow G$  and  $G \rightarrow S$ )
- We take some  $X \subseteq R$  (Say just the attribute  $E$ )
- We ask if two tuples are equal on  $X$ , what is the largest set of attributes on which they must be equal
- We call this set ***the closure of  $X$  with respect to  $F$***  and denote it by  $X_F^+$  (in our case  $E_F^+ = EGS$  and  $S_F^+ = S$ , as is easily seen)
- If it is understood what  $F$  is, we can write just  $X^+$

# ***Operations For Getting A Minimal Cover***

# Getting A Minimal Cover

- This form will be based on trying to store a “concise” representation of FDs
- The core of this will be to find “concise” description of FDs
  - Example: in ESG,  $E \rightarrow S$  was not needed
- We will compute a **minimal cover (also called canonical cover)** for a set of FDs
- The basic idea, simplification of a set of FDs by
  - Combining FDs when possible
  - Getting rid of unnecessary attributes

## ***Removal of Trivial FDs***

- $F = \{ A \rightarrow AB \}$

***is equivalent to***

$$H = \{ A \rightarrow B \}$$

- We could prove it formally, but it is obvious by the definition of  $\rightarrow$

## Union Rule: Combining Right Hand Sides (RHSs)

- $F = \{ AB \rightarrow C, AB \rightarrow D \}$

*is equivalent to and should be converted to*

$$H = \{ AB \rightarrow CD \}$$

- We have discussed this rule before
- Intuitively clear
- Formally we need to prove 2 things
  - $F \models H$  is true; we do this (as we know) by showing that  $AB_F^+$  contains  $CD$ ; easy exercise
  - $H \models F$  is true; we do this (as we know) by showing that  $AB_H^+$  contains  $C$  and  $AB_H^+$  contains  $D$ ; easy exercise
- Note: you **cannot** combine LHSs based on equality of RHS and get an equivalent set of FDS
  - $F = \{ A \rightarrow C, B \rightarrow C \}$  *is stronger than*  $H = \{ AB \rightarrow C \}$

# ***Union Rule: Combining Right Hand Sides (RHSs)***

- Stated formally:

$F = \{ X \rightarrow Y, X \rightarrow Z \}$  ***is as powerful as***  $H = \{ X \rightarrow YZ \}$

- If two rows have the same X value then they have the same Y value and the same Z value.

# ***Simplifying Sets Of FDs***

- At various stages of the algorithm we will have
  - An “old” set of FDs
  - A “new” set of FDs
- The two sets will not vary by “very much”
- We will indicate the parts that do not change by . . .
- Of course, as we are dealing with sets, the order of the FDs in the set does not matter

## ***Simplifying Set Of FDs By Using The Union Rule***

- $X, Y, Z$  are sets of attributes
- Let  $F$  be:

$$\begin{array}{l} \dots \\ X \rightarrow Y \\ X \rightarrow Z \end{array}$$

- Then,  $F$  is equivalent to the following  $H$ :

$$\begin{array}{l} \dots \\ X \rightarrow YZ \end{array}$$

## ***Simplify Set Of FDS By Simplifying LHS***

- Let  $X, Y$  be sets of attributes and  $B$  a single attribute not in  $X$

- Let  $F$  be:

$$\overset{\dots}{X}B \rightarrow Y$$

- Let  $H$  be:

$$\overset{\dots}{X} \rightarrow Y$$

- Can we replace  $F$  by  $H$  without changing the “power” of  $F$ ?
- We can if the closure on  $X$  given functional dependencies  $F$ , denoted  $X_F^+$ , contains  $Y$ 
  - $H$  could only be stronger, but we are proving it is not actually stronger, but equivalent

# ***Simplify Set Of FDS By Simplifying LHS***

- H can only be stronger than F, as we have replaced a weaker FD by a stronger FD
- But if we  $F \models H$  holds, this “local” change does not change the overall power
- Example below
- Replace
  - $AB \rightarrow C$
  - $A \rightarrow B$by (because closure of A contains B in the above functional dependencies)
  - $A \rightarrow C$
  - $A \rightarrow B$

## ***Simplify Set Of FDS By Simplifying RHS***

- Let  $X, Y$  be sets of attributes and  $C$  a single attribute not in  $Y$

- Let  $F$  be:

$$\begin{array}{c} \dots \\ \bar{X} \rightarrow YC \\ \dots \end{array}$$

- Let  $H$  be:

$$\begin{array}{c} \dots \\ \bar{X} \rightarrow Y \\ \dots \end{array}$$

- Can we replace  $F$  by  $H$  without changing the “power” of  $F$ ?
- We do this by showing that  $X_H^+$  contains  $YC$ 
  - $H$  could only be weaker, but we are proving it is not actually weaker, but equivalent

# ***Simplify Set Of FDS By Simplifying RHS***

- H can only be weaker than F, as we have replaced a stronger FD by a weaker FD
- But if we  $H \models F$  holds, this “local” change does not change the overall power
- Example below
- Replace
  - $A \rightarrow BC$
  - $B \rightarrow C$
  - by
  - $A \rightarrow B$
  - $B \rightarrow C$

# Minimal Cover

- Given a set of FDs  $F$ , find a set of FDs  $F_m$ , that is (in a sense we formally define later) minimal
  1. Start with  $F$
  2. Remove all trivial functional dependencies (by removing from the right side of an FD all the attributes that appear on the left side)
  3. Repeatedly apply (in any order you like), until no changes are possible

Union Simplification e.g.  $F = \{ AB \rightarrow C, AB \rightarrow D \}$

becomes  $H = \{ AB \rightarrow CD \}$

- RHS Simplification (e.g.  $\{A \rightarrow BC, B \rightarrow C\}$  becomes  $\{A \rightarrow B, B \rightarrow C\}$ )
- LHS Simplification (e.g.  $\{AB \rightarrow C, A \rightarrow B\}$  becomes  $\{A \rightarrow C, A \rightarrow B\}$ )

What you get is a minimal cover

## ***Minimal Cover For Our Example***

# ***The EmToPrHoSkLoRo Relation***

- The relation deals with employees who use tools on projects and work a certain number of hours per week
- An employee may work in various locations and has a variety of skills
- All employees having a certain skill and working in a certain location meet in a specified room once a week
- The attributes of the relation are:
  - Em: Employee
  - To: Tool
  - Pr: Project
  - Ho: Hours per week
  - Sk: Skill
  - Lo: Location
  - Ro: Room for meeting

## ***The FDs Of The Relation***

- The relation deals with employees who use tools on projects and work a certain number of hours per week
- An employee may work in various locations and has a variety of skills
- All employees having a certain skill and working in a certain location meet in a specified room once a week
- The relation satisfies the following FDs:
  - Each employee uses a single tool:  $Em \rightarrow To$
  - Each employee works on a single project:  $Em \rightarrow Pr$
  - Each tool can be used on a single project only:  $To \rightarrow Pr$
  - An employee uses each tool for the same number of hours each week:  $EmTo \rightarrow Ho$
  - All the employees working in a location having a certain skill always work in the same room (in that location):  $SkLo \rightarrow Ro$
  - Each room is in one location only:  $Ro \rightarrow Lo$

# Sample Instance

	Em	To	Pr	Ho	Sk	Lo	Ro
	Mary	Pen	Research	20	Clerk	Boston	101
	Mary	Pen	Research	20	Writer	Boston	102

	Lakshmi	Oracle	Database	40	Clerk	Trenton	110
	Lakshmi	Oracle	Database	40	Economist	Buffalo	107

## ***Our FDs***

1.  $Em \rightarrow To$
2.  $Em \rightarrow Pr$
3.  $To \rightarrow Pr$
4.  $EmTo \rightarrow Ho$
5.  $SkLo \rightarrow Ro$
6.  $Ro \rightarrow Lo$

## *Run The Algorithm*

- There are no trivial FDs so we continue with the given FDs:
  1.  $Em \rightarrow ToPr$
  2.  $To \rightarrow Pr$
  3.  $EmTo \rightarrow Ho$
  4.  $SkLo \rightarrow Ro$
  5.  $Ro \rightarrow Lo$

## ***Run The Algorithm***

- Using the union rule, we combine RHS of 1 and 2, getting:
  1.  $Em \rightarrow ToPr$
  2.  $To \rightarrow Pr$
  3.  $EmTo \rightarrow Ho$
  4.  $SkLo \rightarrow Ro$
  5.  $Ro \rightarrow Lo$

## *Run The Algorithm*

- No additional RHS can be combined, so we check whether there are any redundant attributes.
- We start with FD 1, where we attempt to remove an attribute from RHS
  - We check whether we can remove To from the right hand side. This is possible if we can derive  $Em \rightarrow To$  using
$$\begin{aligned}Em &\rightarrow Pr \\To &\rightarrow Pr \\EmTo &\rightarrow Ho \\SkLo &\rightarrow Ro \\Ro &\rightarrow Lo\end{aligned}$$
Computing the closure of Em using the above FDs gives us only EmPr, so the attribute To must be kept.

## ***Run The Algorithm (RHS simplification)***

- We check whether we can remove Pr. This is possible if we can derive  $Em \rightarrow Pr$  using

$Em \rightarrow To$

$To \rightarrow Pr$

$EmTo \rightarrow Ho$

$SkLo \rightarrow Ro$

$Ro \rightarrow Lo$

Computing the closure of Em using the above FDs gives us EmToPrHo, so the attribute Pr is redundant (or equivalently, the dependency  $Em \rightarrow Pr$  is redundant)

# *Run The Algorithm*

- We now have
  1.  $Em \rightarrow To$
  2.  $To \rightarrow Pr$
  3.  $EmTo \rightarrow Ho$
  4.  $SkLo \rightarrow Ro$
  5.  $Ro \rightarrow Lo$
- No RHS can be combined, so we continue attempting to remove redundant attributes. The next one is FD 3, where we attempt to remove an attribute from LHS
  - We check if  $Em$  can be removed. This is possible if we can derive  $To \rightarrow Ho$  using *all* the FDs. Computing the closure of  $To$  using the FDs gives  $ToPr$ , and therefore  $Em$  cannot be removed
  - We check if  $To$  can be removed. This is possible if we can derive  $Em \rightarrow Ho$  using *all* the FDs. Computing the closure of  $Em$  using the FDs gives  $EmToPrHo$ , and therefore  $To$  can be removed

# *Run The Algorithm*

- We now have
  1.  $Em \rightarrow To$
  2.  $To \rightarrow Pr$
  3.  $Em \rightarrow Ho$
  4.  $SkLo \rightarrow Ro$
  5.  $Ro \rightarrow Lo$
- We can now combine RHS of 1 and 3 and get
  1.  $Em \rightarrow ToHo$
  2.  $To \rightarrow Pr$
  3.  $SkLo \rightarrow Ro$
  4.  $Ro \rightarrow Lo$

# *Run The Algorithm*

- We now have
  1.  $Em \rightarrow ToHo$
  2.  $To \rightarrow Pr$
  3.  $SkLo \rightarrow Ro$
  4.  $Ro \rightarrow Lo$
- No RHS can be combined, so we continue attempting to remove redundant attributes.
- The first one is FD 1, where we attempt to remove an attribute from RHS

We check if To can be removed. This is possible if we can derive  $Em \rightarrow ToHo$  using

$Em \rightarrow Ho$   
 $To \rightarrow Pr$   
 $SkLo \rightarrow Ro$   
 $Ro \rightarrow Lo$

$Em^+$  is  $EmHo$  only so To cannot be removed

## *Run The Algorithm*

We check if  $H_o$  can be removed. This is possible if we can derive  $E_m \rightarrow ToHo$  using

$E_m \rightarrow To$   
 $To \rightarrow Pr$   
 $SkLo \rightarrow Ro$   
 $Ro \rightarrow Lo$

$E_m^+$  is  $EmToPr$  only, so  $H_o$  cannot be removed

- The next one is FD 3, where we attempt to remove an attribute from LHS

We have actually checked this before and nothing has changed that could impact the decision so we will not do it again here.

# ***Run The Algorithm***

- Nothing else can be done
  - Therefore we are done
  - We have computed a minimal cover for the original set of FDs
- 
- Important: In your homework do not skip any steps
  - ***When you prove equivalence of the “old” set with the “new” set, compute closure of an appropriate set of attributes as we have done***

# ***Minimal Cover***

## ***Concise and Formal Definition***

- A set of FDs,  $F_m$ , is a **minimal cover** for a set of FD  $F$ , if and only if
  1.  $F_m$  is minimal, that is
    1. No two FDs in it can be combined using the union rule
    2. No attribute can be removed from a RHS of any FD in  $F_m$  without changing the power of  $F_m$
    3. No attribute can be removed from a LHS of any FD in  $F_m$  without changing the power of  $F_m$
  2.  $F_m$  is equivalent in power to  $F$
- Note that there could be more than one minimal cover for  $F$ , as we have not specified the order of applying the simplification operations; they can be applied in any order
- Note that to **prove** that  $F_m$  is a minimal cover it is sufficient just to run the algorithm and show that it does not result in any simplifications

## ***How About EGS***

- Applying to algorithm to EGS with
  1.  $E \rightarrow G$
  2.  $G \rightarrow S$
  3.  $E \rightarrow S$
- Using the union rule, we combine 1 and 3 and get
  1.  $E \rightarrow GS$
  2.  $G \rightarrow S$
- Simplifying right hand side of 1 (based on functional dependency 2), we get
  1.  $E \rightarrow G$
  2.  $G \rightarrow S$
- We automatically got the two “important” FDs!

# ***Getting A Decomposition***

# ***An Algorithm For “An Almost” 3NF Lossless-Join Decomposition***

- Input: relation schema  $R$  and a set of FDs  $F$
- Output: almost-decomposition of  $R$  into  $R_1, R_2, \dots, R_n$ , each in 3NF
- Algorithm
  1. If all the FDs are trivial, there is nothing to do, otherwise
  2. Produce  $F_m$ , a minimal cover for  $F$
  3. For each  $X \rightarrow Y$  in  $F_m$  create a new relation schema  $XY$
  4. For every new relation schema that is a subset (including being equal) of another new relation schema (that is the set of attributes is a subset of attributes of another schema or the two sets of attributes are equal) remove this relation schema (the “smaller” one or one of the equal ones); but if the two are equal, need to keep one of them
  5. The set of the remaining relation schemas is an “almost final decomposition”

## ***Back To Our Example***

- For our EmToPrHoSkLoRo example, we previously computed the following minimal cover:
  1.  $\text{Em} \rightarrow \text{ToHo}$
  2.  $\text{To} \rightarrow \text{Pr}$
  3.  $\text{SkLo} \rightarrow \text{Ro}$
  4.  $\text{Ro} \rightarrow \text{Lo}$

# ***Creating Relations***

- Create a relation for each functional dependency
- We obtain the relations:
  1. EmToHo
  2. ToPr
  3. SkLoRo
  4. LoRo

# ***Removing Redundant Relations***

- LoRo is a subset of SkLoRo, so we remove it
- We obtain the relations:
  1. EmToHo
  2. ToPr
  3. SkLoRo

## ***How About EGS***

- The minimal cover was
  1.  $E \rightarrow G$
  2.  $G \rightarrow S$
- Therefore the relations obtained were:
  1. EG
  2. GS
- And this is exactly the decomposition we thought was the best!

# ***Assuring Storage Of A Global Key***

- If no relation contains a key of the original relation, add a relation whose attributes form such a key
- Why do we need to do this?
  - Because otherwise we may not have a decomposition
  - Because otherwise the decomposition may not be lossless

# ***Why It Is Necessary To Store A Global Key Example***

- Consider the relation LnFn:
  - Ln: Last Name
  - Fn: First Name
- There are no FDs
- The relation has only one key:
  - LnFn
- Our algorithm (without the key included) produces no relations
- A condition for a decomposition: Each attribute of R has to appear in at least one  $R_i$
- So we did not have a decomposition
- But if we add the relation consisting of the attributes of the key
  - We get LnFn (this is fine, because the original relations had no problems and was in a good form, actually in BCNF, which is always true when there are no (nontrivial) FDs)

# ***Why It Is Necessary To Store A Global Key Example***

- Consider the relation: LnFnVaSa:
  - Ln: Last Name
  - Fn: First Name
  - Va: Vacation days per year
  - Sa: Salary
- The functional dependencies are:
  - $Ln \rightarrow Va$
  - $Fn \rightarrow Sa$
- The relation has only one key
  - LnFn
- The relation is not in 3NF
  - $Ln \rightarrow Va$ :      Ln does not contain a key and Va is not in any key
  - $Fn \rightarrow Sa$ :      Fn does not contain a key and Sa is not in any key

# ***Why It Is Necessary To Store A Global Key Example***

- Our algorithm (without the key being included) will produce the decomposition
  1. LnVa
  2. FnSa
- This is not a lossless-join decomposition
  - In fact we do not know who the employees are (what are the valid pairs of LnFn)
- So we decompose
  1. LnVa with (primary) key Ln
  2. FnSa with (primary) key Fn
  3. LnFn with (primary) key LnFn

## ***Assuring Storage Of A Global Key***

- If no relation contains a key of the original relation, add a relation whose attributes form such a key
- It is easy to test if a “new” relation contains a key of the original relation
- Compute the closure of the relation with respect to all FDs (either original or minimal cover, it's the same) and see if you get all the attributes of the original relation
- If not, you need to find some key of the original relation
- We have studied this with the lattices.

# ***Applying The Algorithm to EGS***

- Applying the algorithm to EGS, we get our desired decomposition:
  - EG
  - GS
  
- And the “new” relations are in BCNF too, though we guaranteed only 3NF!

## *Returning to Our Example*

- We pick the decomposition
  1. EmToHo
  2. ToPr
  3. SkLoRo
  4. EmSkLo
  
- We have the minimal set of FDs of the simplest form (before any combinations)
  1.  $Em \rightarrow ToHo$
  2.  $To \rightarrow Pr$
  3.  $SkLo \rightarrow Ro$
  4.  $Ro \rightarrow Lo$

## *Returning to Our Example*

- Everything can be described as follows:
- The relations, their keys, and FDs that need to be explicitly mentioned are:
  1. EmToHo      key: Em
  2. ToPr      key: To
  3. SkLoRo      key: SkLo, key SkRo, and functional dependency  $Ro \rightarrow Lo$
  4. EmSkLo      key: EmSkLo
- In general, when you decompose as we did, a relation may have several keys and satisfy several FDs that do not follow from simply knowing keys
- In the example above there was one relation that had such an FD, which made it automatically not a BCNF relation (but by our construction a 3NF relation)

## ***Back to SQL DDL***

- How are we going to express in SQL what we have learned?
- We need to express:
  - keys
  - functional dependencies
- Expressing keys is very easy, we use the PRIMARY KEY and UNIQUE keywords
- Expressing functional dependencies is possible also by means of a CHECK condition (If your tables are normalized, no need for this)
  - What we need to say for the relation SkLoRo is that each tuple satisfies the following condition

There are no tuples in the relation with the same value of Ro and different values of Lo

# ***Denormalization***

- After Normalization, we may want to ***denormalize***
- The idea is to introduce redundant information in order to speed up some queries
- So the design not so clean, but more efficient, e.g. (storeid, sales, day), (storeid, city), (city, state)
- Vs. (storeid, city, state, sales, day), (storeid, city), (city, state)
- If the data doesn't change too much the second denormalized schema might be faster for certain queries?
- Which queries?
- Why denormalized?

# ***DB Design Process (Roadmap)***

- Produce a good ER diagram, thinking of all the issues
- Specify all the functional dependencies (business rules) that you know about
- Produce relational implementation
- Normalize each table to whatever extent feasible

# ***A Review And Some Additional Material***

# ***What We Will Cover Here***

- Elaborate on the concept of lossless-join decomposition
- Review concepts dealing with functional dependencies
- Review algorithms
- Add some material extending previous material

# Lossless-Join Decomposition

- We consider a decomposition, replacing

R	Name	<u>SSN</u>	DOB	Grade	Salary
	A	121	2367	2	80
	A	132	3678	3	70
	B	101	3498	4	70
	C	106	2987	2	80

by two tables

S	Name	<u>SSN</u>	DOB	Grade
	A	121	2367	2
	A	132	3678	3
	B	101	3498	4
	C	106	2987	2

T	<u>Grade</u>	Salary
	2	80
	3	70
	4	70

# Lossless-Join Decomposition

- Given S and T, we can reconstruct R using *natural join*

S	Name	<u>SSN</u>	DOB	Grade
	A	121	2367	2
	A	132	3678	3
	B	101	3498	4
	C	106	2987	2

T	<u>Grade</u>	Salary
	2	80
	3	70
	4	70

```
SELECT INTO R
Name, SSN, DOB, S.Grade AS Grade, Salary
FROM T, S
WHERE T.Grade = S.Grade;
```

R	Name	<u>SSN</u>	DOB	Grade	Salary
	A	121	2367	2	80
	A	132	3678	3	70
	B	101	3498	4	70
	C	106	2987	2	80

# ***Not Lossless-Join Decomposition***

- We consider a different decomposition, replacing

R	Name	<u>SSN</u>	DOB	Grade	Salary
	A	121	2367	2	80
	A	132	3678	3	70
	B	101	3498	4	70
	C	106	2987	2	80

by two tables

S	Name	<u>SSN</u>	DOB	Salary
	A	121	2367	80
	A	132	3678	70
	B	101	3498	70
	C	106	2987	80

T	<u>Grade</u>	Salary
	2	80
	3	70
	4	70

# Not Lossless-Join Decomposition

- When we reconstruct by joining the new tables

S	Name	<u>SSN</u>	DOB	Salary	T	<u>Grade</u>	Salary
	A	121	2367	80		2	80
	A	132	3678	70		3	70
	B	101	3498	70		4	70
	C	106	2987	80			

We get a table that contains two different values of Grade for SSN = 132 and SSN = 101, which is not correct

- We do not know which Grades are correct for those SSNs

R	Name	<u>SSN</u>	DOB	Grade	Salary
	A	121	2367	2	80
	A	132	3678	3	70
	B	101	3498	4	70
	C	106	2987	2	80
	A	132	3678	4	70
	B	101	3498	3	70

# Only Lossless-Join Decompositions Are Acceptable

- Formally, a decomposition of R into is **lossless-join** if the natural join of the new tables is equal to R, **for all instances** of R satisfying the given constraints
- Given several tables, say R1, R2, ..., Rn, their **natural join** is computed using the following “template”:

```
SELECT INTO R  
one copy of each column name  
FROM R1, R2, ..., Rn  
WHERE equal-named columns have to be equal
```

- The intuition is that R was “decomposed” into R1, R2, ..., Rn by appropriate SELECT statements, and now we are putting R1, R2, ..., Rn back together to reconstruct the original R

# ***Functional Dependencies*** ***(Abbreviation: FDs)***

- Let  $X$  and  $Y$  be sets of columns, then:

$X$  ***functionally determines***  $Y$ , written  $X \rightarrow Y$

if and only if

any two rows that are equal on (all the attributes in)  $X$   
must be equal on (all the attributes in)  $Y$

- In simpler terms, less formally, but really the same, it means that:

***If a value of  $X$  is specified, it “determines” some (specific) value of  $Y$ ; in other words:  $Y$  is a function of  $X$***

- We will assume that for a given FD  $X \rightarrow Y$  attributes in  $X$  cannot have the value of NULL: attributes of  $X$  correspond to arguments of a function
- We will generally look at ***sets of FDs*** and will denote them as needed by  **$M$**  and  **$N$**

## Trivial FDs

- If  $Y \subseteq X$  then FD  $X \rightarrow Y$ 
  - Always holds
  - Does not say anything
- Such FD is called *trivial*
- Can always remove the “trivial part” from an FD without changing the constraint expressed by that FD
- Example: Replace
$$ABCD \rightarrow CDE$$
by
$$ABCD \rightarrow E$$

Having CD on the right side does not add anything

## ***Union Rule/Property***

- An FD with n attributes on the right hand side

$$X \rightarrow A_1 A_2 \dots A_n$$

is equivalent to the set of n FDs

$$X \rightarrow A_1$$

$$X \rightarrow A_2$$

....

$$X \rightarrow A_n$$

- Example:

$$ABC \rightarrow DEFG$$

is equivalent to set of 4 FDs

$$ABC \rightarrow D$$

$$ABC \rightarrow E$$

$$ABC \rightarrow F$$

$$ABC \rightarrow G$$

# Closures of a Sets of Attributes

- In general, we have a concept of a **the closure** of a set of attributes in a relational schema  **$R$**
- We are given a set of functional dependencies, say  **$M$**
- Let  **$X$**  be a set of attributes,
- **$X_M^+$**  is the set of all the attributes whose values are “determined” by the values of  $X$  because of  $M$ 
  - If  $M$  is understood, we do not need to write it and can just write  **$X^+$**

# Computing Closures Of Sets Of Attributes

- There is a very simple algorithm to compute  $X^+$  (given some set of FDs)
  1. Let  $Y = X$
  2. Whenever there is an FD, say  $V \rightarrow W$ , such that
    1.  $V \subseteq Y$ , and
    2.  $W - Y$  is not emptyadd  $W - Y$  to  $Y$
  3. At termination  $Y = X^+$
- The algorithm is very efficient
- Each time we look at all the functional dependencies
  - Either we can apply at least one functional dependency and make  $Y$  bigger (the biggest it can be are all attributes), or
  - We are finished

# Keys Of Tables

- Given  $R$  (relation schema which is always denoted by its set of attributes), satisfying a set of FDs, a set of attributes  $X$  of  $R$  is a **key** (in information technology sometimes called “candidate key”), if and only if:
  - $X^+ = R$ .
  - For any  $Y \subseteq X$  such that  $Y \neq X$ , we have  $Y^+ \neq R$ .
- Note that if  $R$  does not satisfy any (nontrivial) FDs, then  $R$  is the only key of  $R$
- Example, if a table is  $R(\text{FirstName}, \text{LastName})$  without any functional dependencies, then its key is just the pair  $(\text{FirstName}, \text{LastName})$

# ***Anomalies And Boyce-Codd Normal Form (BCNF)***

- We are given ***R*** (relation schema) and ***M*** (set of FDs)
- We have an anomaly whenever
$$\mathbf{X \rightarrow Y}$$
 is non-trivial and holds  
but
$$\mathbf{X \text{ does not contain a key of } R}$$
 (sometimes phrased:  
 $\mathbf{X}$  is not a superkey of  $\mathbf{R}$ )
- Because there could be different tuples with the same value of  $\mathbf{X}$  and they all have to have the same value of  $\mathbf{Y}$
- A relation is in ***BCNF*** if anomalies as described in this slide do not happen

# ***How To Prove That A Relation Is Not In BCNF***

- To prove that relation  $R$  is not in BCNF it is enough to show that there is a non-trivial FD  $X \rightarrow Y$  and  $X$  does not contain a key of  $R$
- And to show that  $X$  does not contain a key of  $R$  it is enough to show that  $X^+ \neq R$
- **This is important, simple, and useful**

# ***Some Normal Forms***

- We have discussed several additional normal forms pertaining to FDs
  - Second Normal Form (2NF)
  - Third Normal Form (3NF)
- We did not look at the most general definitions
- Let us review what we did using an old example
- We have, in general, FDs of the form  $X \rightarrow Y$
- But by the **union** rule, we can **decompose** them and consider FDs of the form  $X \rightarrow A$ , where **A** is a single attribute

# Classification Of FDs

## (Our Old Example Focusing Only on One Key)

- The three “not from the full key” dependencies are classified as:
  - **Partial dependency:** From a part of the primary key to outside the key
  - **Transitive dependency:** From outside the key to outside the key (this our informal phrasing)
  - **Into key dependency:** From outside the key into (all or part of) the key
- 
- But what if we have  $X \rightarrow Y$  where  $X$  is partially in the key and partially outside the key?

# ***It is Incomplete to Focus on Only One Key (The Primary Key)***

- By looking at the diagram we immediately can deduce that ST is also a key
  - Because T determines C and therefore as SC determined R, so did ST
- And we discussed it too.

# ***General Definition of Some Normal Forms***

- Let R be relation schema
- We will list what is permitted for three normal forms
- We will include an obsolete normal form, which is still sometimes considered by practitioners: second normal form (2NF)
- It is obsolete, because we can always find a desired decomposition in relations in 3NF, which is better than 2NF
- The interesting one is a general definition of 3NF
- Note: no discussion of which key is chosen to be primary as this is formally really “an arbitrary decision” though perhaps important for the application

# Which FDs Are **Allowed** For Some Normal Forms

Consider  **$X \rightarrow A$**  ( **$X$**  a set,  **$A$**  a single attribute)

BCNF	3NF	2NF
$X \rightarrow A$ is trivial ( $A$ is inside $X$ )	$X \rightarrow A$ is trivial ( $A$ is inside $X$ )	$X \rightarrow A$ is trivial ( $A$ is inside $X$ )
$X$ contains a key	$X$ contains a key	$X$ contains a key
	$A$ is inside some key (informally: $X \rightarrow A$ into a key, but $X$ can overlap a key)	$A$ is inside some key (informally: $X \rightarrow A$ into a key, but $X$ can overlap a key)
		$X$ not a proper subset of any/some key

# ***An FD From a Key Into Itself Is Not Possible***

- It is not possible to have a non-trivial functional dependency from a part of key into that same key
- Proof by example:

- In such a situation ABC is “too big” and actually BC is a key (and also the drawing does not follow standards)

## ***Example: Relation in 3NF And Not in BCNF***

- Given functional dependencies:  $ABC \rightarrow DE$  and  $CD \rightarrow A$
- $ABC$  is a key and designated as primary
- This relation is not in BCNF as we have  $CD \rightarrow A$  and  $CD$  does not contain a key as is easily seen
- But  $CD \rightarrow A$  is of the form: (something not containing a key)  $\rightarrow$  (attribute in a key) and this is permitted by 3NF
- Note there is another key that could have been the primary key:  $BCD$
- Originally people were confused as they considered only one key and did not realize that in general  $3NF \neq BCNF$

## *If Only One Key Then 3NF $\Rightarrow$ BCNF*

- Proof by **contradiction** (using example, but really general)
- Assume that a relation is in 3NF but not in BCNF and there is only one key
- Then we have a functional dependency that is permitted by 3NF but not permitted by BCNF, that is of the form  
(something not containing a key)  $\rightarrow$  (attribute in a key)

- Example

ABC is a key  
and  $CD \rightarrow A$  holds

- Then we see that **BCD** is a key also, so we have more than one key
- So we proved: **if** 3NF and only one key **then** BCNF

## ***Relative Power of FDS: Simplify RHS***

- If attributes removed from RHS (right hand side), the functional dependency becomes weaker
- Changing from  $ABCD \rightarrow EFG$  to  $ABCD \rightarrow EF$  the dependency becomes weaker
- Intuitively, after the simplification, we start with the same assumptions and deduce fewer conclusions

## ***Relative Power of FDS: Simplify LHS***

- If attributes removed from LHS (left hand side), the functional dependency becomes stronger
- Changing from  $ABCD \rightarrow EFG$  to  $ABC \rightarrow EFG$  the dependency becomes stronger
- Intuitively, after the simplification, we start with fewer assumptions and deduce the same conclusions

## ***A Typical Step in Computing Minimal Cover***

- We have a set  $M$  of functional dependencies
- $M$  contains two functional dependencies with the same left hand side, say

$$X \rightarrow EFG$$

$$X \rightarrow GH$$

- We replace these functional dependencies by one functional dependency

$$X \rightarrow EFGH$$

- And we get a set  $N$  of functional dependencies
- $N$  is equivalent to  $M$

## *A Typical Step in Computing Minimal Cover*

- We have a set  $M$  of functional dependencies.
- $M$  contains a functional dependency with more than one attribute in the RHS, say

$$X \rightarrow EFG$$

- We replace this functional dependency by
- $$X \rightarrow EF$$
- And we get a set  $N$  of functional dependencies

- $N$  can only be weaker (in power) than  $M$

- $N$  is equivalent (in power) to  $M$   
if and only if

we can “prove the stronger functional dependency”:

$$X_N^+ \text{ contains } EFG$$

## *A Typical Step in Computing Minimal Cover*

- We have a set  $M$  of functional dependencies.
- $M$  contains a functional dependency with more than one attribute in the LHS, say

$$ABCD \rightarrow Y$$

- We replace this functional dependency by
- $$ABC \rightarrow Y$$
- And we get a set  $N$  of functional dependencies

- $N$  can only be stronger (in power) than  $M$

- $N$  is equivalent to  $M$

if and only if

we can “prove the stronger functional dependency”:

$$ABC_M^+ \text{ contains } Y$$

# ***The Goal***

- Given a table  $R$  satisfying a set of FDs  $M$ , decompose it into tables:  $R_1$  satisfying  $M_1$ ,  $R_2$  satisfying  $M_2$ , ...,  $R_k$  satisfying  $M_k$ , such that
- The decomposition is lossless join: can recover  $R$  from  $R_1, R_2, \dots, R_k$  using natural join
- Dependencies are preserved: making sure that (after changes to the database) *if*  $R_1$  satisfies  $M_1$ ,  $R_2$  satisfies  $M_2$ , ...,  $R_k$  satisfies  $M_k$ , **then** that if we recover  $R$  it will satisfy  $M$
- $R_1, R_2, \dots, R_k$  are all in 3NF (and if we are lucky also in BCNF)

## *Sketch of The Procedure*

- Compute a minimal cover  $N$  for  $M$
- Create a table for each functional dependency in  $N$
- Remove redundant tables that is

Remove a table if its set of columns is a subset of the set of columns of another table

But, of course if we get two identical tables, we remove only one of them

- Check if at least one table contains a global key: just compute closure of its attributes using  $M$  (or  $N$ , likely faster) and see if you get all of  $R$
- If no table contains a global key, find one global key (using heuristics or otherwise) and add a table whose columns are the attributes of the global key you found

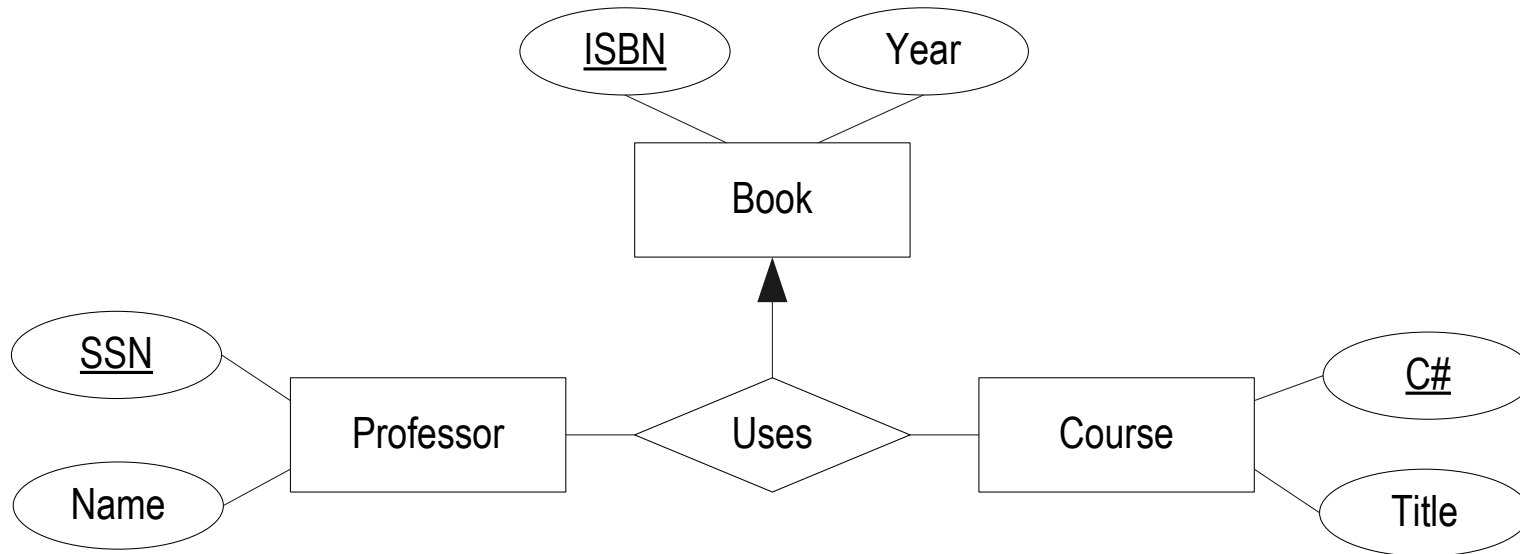

## ***Revisiting an Old Example***

# An Old Example

- We want to specify that professors use books in courses when teaching
- There is a constraint
  - Only one book can be used in a course
- Therefore, Book is a (partial) function of Course (only)
  - Given  $c$  in Course there is at most one  $b$  in Book
- ***We need to annotate the diagram below*** that in the ternary relationship (Professor, Course, Book) the many-to-one relationship (indicated by an arrow) is between Course and Book, as otherwise we will think it is between (Professor, Course) and Book

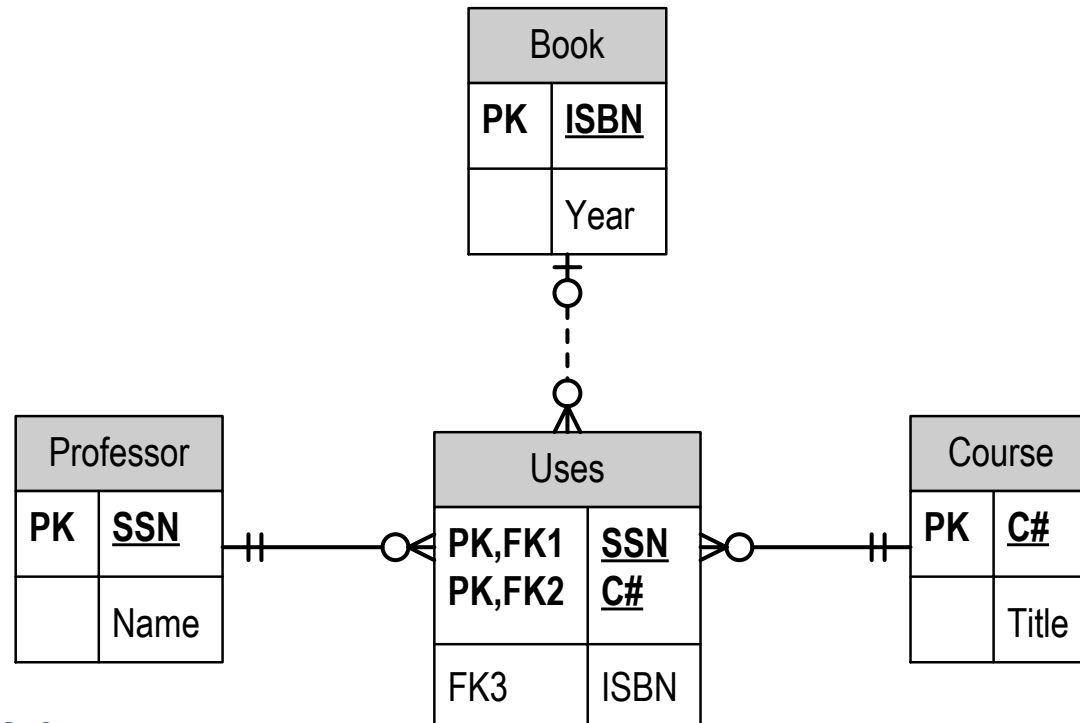

# *An Old Example*

## ■ Annotations

- The many to-one-relationship depicted by the arrow is only from Course to Book (the Book depends only on Course and not on the pair (Professor, Course))

# A Straightforward Relational Implementation

- Annotation
  - Book is a (partial) function only of Course
- The tables with primary keys and additional FDs and their normal forms are
  - Professor(SSN, Name); in BCNF
  - Course(C#, Title); in BCNF
  - Book(ISBN, Year); in BCNF
  - Uses(SSN, C#, ISBN);  $C\# \rightarrow ISBN$ ; in 1NF

# Normalizing

- Replace

- Uses(SSN, C#, ISBN);  $C\# \rightarrow ISBN$

By

- Uses(SSN, C#) (Who teaches what)
- Uses(C#, ISBN) (Which book is assigned in a course)

- So let's rename

- Teaches(SSN, C#) (Who teaches what)
- Assigned(C#, ISBN) (Which book is assigned in a course)

- All the tables

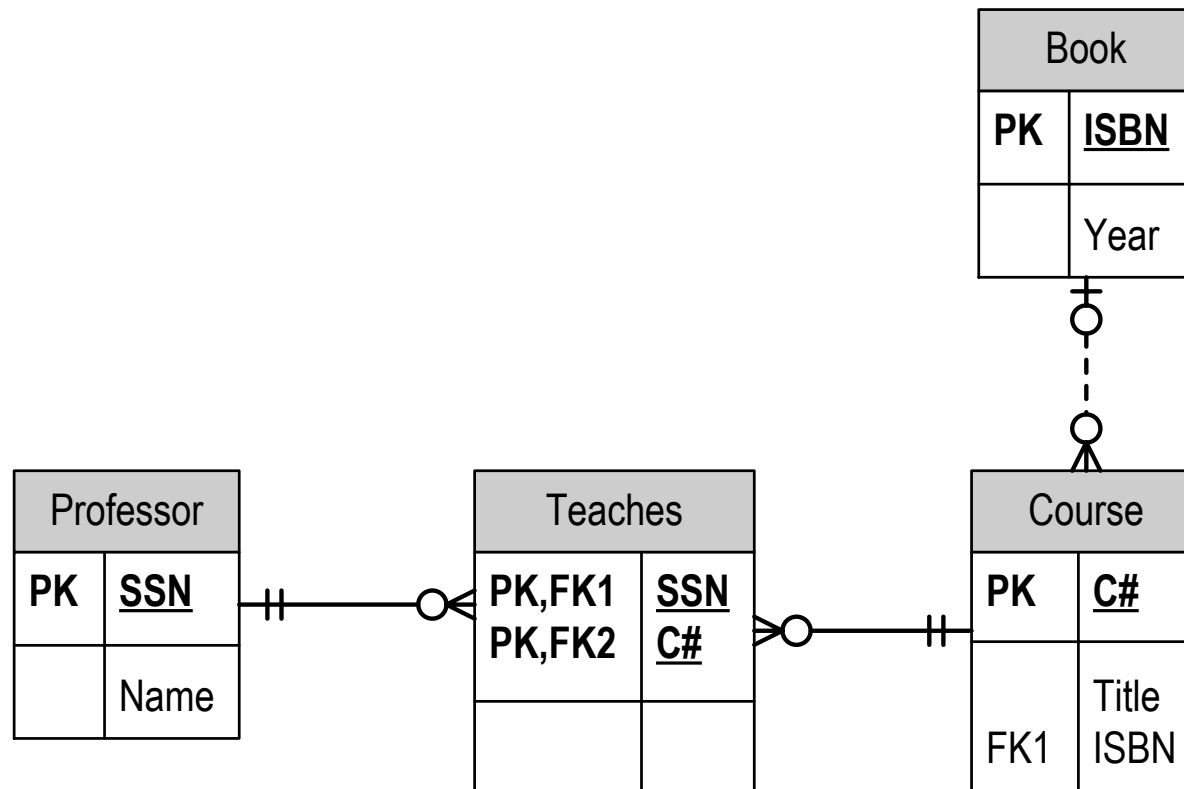

- Professor(SSN, Name); in BCNF
- Course(C#, Title); in BCNF
- Book(ISBN, Year); in BCNF
- Teaches(SSN, C#); in BCNF
- Assigned(C#, ISBN); in BCNF

# Normalizing

- All the tables
  - Professor(SSN, Name)
  - Course(C#, Title)
  - Book(ISBN, Year)
  - Teaches(SSN, C#)
  - Assigned(C#, ISBN)
- We can combine
  - Course(C#, Title)
  - Assigned(C#, ISBN)
- All the tables
  - Professor(SSN, Name)
  - Course(C#, Title, ISBN)
  - Book(ISBN, Year)
  - Teaches(SSN, C#)

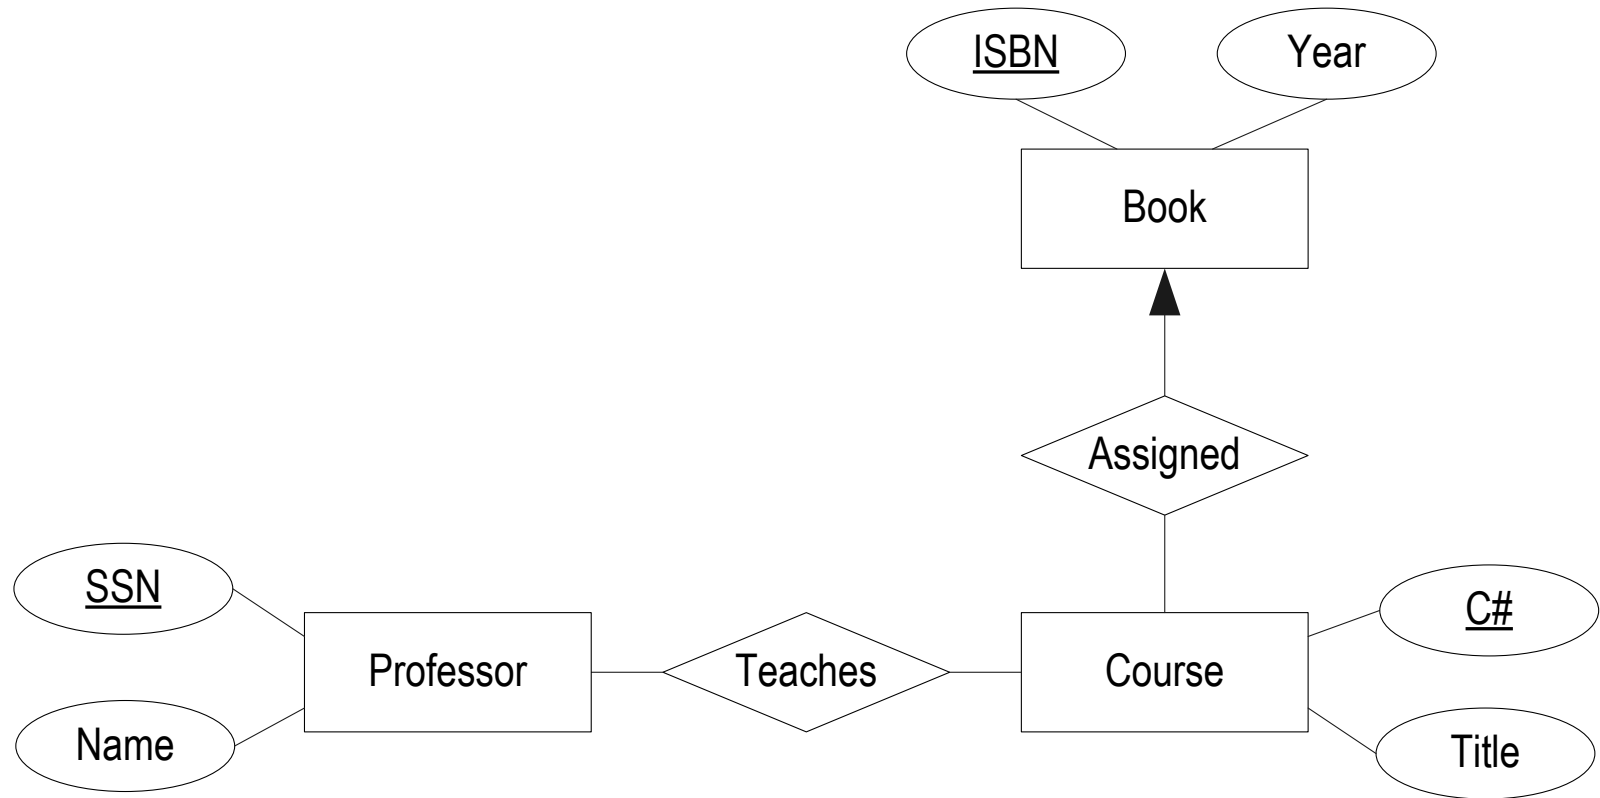

# ***Better Relational Implementation***

- No need for annotations!
- Whoever produced the original ER diagram did not think completely through the application

# Better ER Diagram

- No annotations needed!

# ***Key Ideas***

# ***Key Ideas***

- Need for decomposition of tables
- Functional dependencies
- Some types of functional dependencies:
  - Partial dependencies
  - Transitive dependencies
  - Into full key dependencies
- First Normal Form: 1NF
- Second Normal Form: 2NF
- Third Normal Form: 3NF
- Boyce-Codd Normal Form: BCNF
- Removing redundancies
- Lossless join decomposition
- Preservation of dependencies
- 3NF vs. BCNF

# ***Key Ideas***

- Multivalued dependencies
- Fourth Normal Form: 4NF
- Minimal cover for a set of functional dependencies
- Algorithmic techniques for finding keys
- Algorithmic techniques for computing a minimal cover
- Algorithmic techniques for obtaining a decomposition of relation into a set of relations, such that
  - The decomposition is lossless join
  - Dependencies are preserved
  - Each resulting relation is in 3NF
- Denormalization after Normalization
